Mining and Exploration

Satellite Image Processing

With the variety of remotely sensed images that are available today, multi – spectral imaging is one that if expertly processed, can assist in the detection of alteration halos that are associated with hydrothermal activity and mineral deposition. These images are being used more frequently by exploration companies and considered an essential part of their exploration planning.

Satellite image processing and the creation of high resolution maps that are integrated into a geographic information system can refine, expedite, and reduce the time and cost of a particular mineral search. Image processing is one of the services offered by Medusa Geo-Consulting.
